

YaPcore releases (v1.0.0.0)

All first-party artifacts share version **1.0.0.0** (Gradle `version` , plugin `plugin.yml` , Link `link-plugin.json`).

Release notes: [RELEASE_NOTES.md](#)

License: release trees include root `LICENSE` (GNU GPLv3). See [LICENSING.md](#).

Game jar: product path expects **YaP-Folia** (`lib/yap-folia-26.2.jar`) built via `./scripts/build-yap-folia.sh` . Stock Fill Folia is not the release default. Build with `./scripts/build-yap-folia.sh` .

Build commands

Task	Output
<code>./scripts/build-yap-folia.sh</code>	<code>lib/yap-folia-26.2.jar</code> — required for product path
<code>gradle assembleRelease</code>	<code>build/dist/yapcore-release/</code> — linux/ + windows/ full trees (all plugins)
<code>gradle assembleRelease - PyapGameplay=false</code>	Slim CORE+NETWORK only (no vehicles / MMO / stacker)
<code>gradle publishReleasesFolder</code>	<code>releases/<version>/</code> — trees + linux/windows zips + suite zips
Git tag <code>1.0.0.0</code> or <code>v*</code> push	GitHub Actions → <code>yapcore-release-linux.zip</code> + <code>- windows.zip</code>
<code>gradle assembleNetworkSuite</code>	<code>build/dist/yap-network-suite.zip</code> — YaP Link + native link plugins
<code>gradle assembleGameplaySuite</code>	<code>build/dist/yap-gameplay-suite.zip</code> — GAMEPLAY plugins/modules (standalone)
<code>gradle assembleAddonsRelease</code>	<code>build/dist/yap-addons-release.zip</code> — example vehicle addon
<code>gradle assemblePluginDist</code>	<code>build/dist/yap-plugins/</code> — flat jar mirror by tier
<code>gradle assembleAllReleases</code>	Full box + all standalone zips (under <code>build/dist/</code>)

Durable release folder

```
./scripts/build-yap-folia.sh
gradle publishReleasesFolder
```

```
# → releases/1.0.0.0/
#   yapcore-release/linux/   yapcore-release/windows/
#   yapcore-release-linux.zip yapcore-release-windows.zip
#   yap-network-suite.zip   yap-gameplay-suite.zip   yap-addons-release.zip
```

The entire `releases/` directory is **gitignored** (local artifacts only). Rebuild anytime with the same task.

After Link wire fixes: `publishReleasesFolder` refreshes `yap-link.jar` inside the `trees/zips`. Also copy the shadow jar to **repo-root** `yap-link.jar` — the Swing/web GUI `LinkProcessManager` prefers that path over `build/libs`.

Linux / Windows full box

Each OS folder is self-contained:

- `yapcore.jar` — YaPcore chassis + embedded web dashboard
- `lib/yap-folia-*.jar` — **YaP-Folia** game (when builder ran `build-yap-folia.sh`)
- `yap-link.jar` + `link-data/` — native multi-backend proxy (`0.6.0-phase6`)
- `plugins/` — CORE+NETWORK first-party stack
- `modules/` — fine-tune packaging modules
- `resourcepacks/` — default client pack
- `config/` , `deploy/nginx` , `deploy/mariadb` , `docs/` , launch scripts

Launch:

```
# Linux
cd build/dist/yapcore-release/linux && ./start.sh --fg

# Windows
cd build\dist\yapcore-release\windows
start.cmd -Fg
```

See [WINDOWS.md](#) and [MARIADB.md](#).

Standalone add-ons

Zip	Contents	Default in full box?
yap-network-suite.zip	Link proxy + chat/mod/selector/tab/discord bridge plugins	Yes (<code>link-data/plugins/</code>)
yap-gameplay-suite.zip	yap-vehicles, yap-stacker, yap-gameplay-knobs + modules	Also included in the full box

Zip	Contents	Default in full box?
yap-addons-release.zip	examples/yap-vehicle-addon built jar + source	No — author reference

Repo layout discipline

- First-party code: `yap-first-party/`
- YaP-Folia: `vendor/folia/` + `QUICK_START.md`
- Gradle split: `build.gradle.kts` + `gradle/yap-product.gradle.kts`, `yap-release.gradle.kts`, `yap-packaging.gradle.kts`
- **Do not commit** live kernel/link state (`folia-kernel/logs`, `usercache`, `ops`, `link-data/link.properties`, plugin config dirs) — enforced by `.gitignore`

Refresh release zips (same version)

When docs/plugins change but the product version stays **1.0.0.0**:

```
./scripts/build-yap-folia.sh # if Folia fork patches changed
gradle publishReleasesFolder # refreshes releases/1.0.0.0/ trees + zips
```

Update `RELEASE_NOTES.md` “After 1.0.0.0” — do **not** change Gradle `version`.

Version bump checklist (new tag only)

1. Root `build.gradle.kts` `version = "..."`
2. Each subproject `build.gradle.kts` + `plugin.yml` / `link-plugin.json`
3. Rebuild YaP-Folia + `gradle assembleAllReleases` / `publishReleasesFolder`
4. Tag: e.g. `1.0.0.0` or later `1.x.y.z` (also accepted: `v...`)
